

Lecture outline

- What is a resource?
- Multilayer problems
- Modeling resources
- A battery storage application

What is a resource?

- What is a resource?

What is a resource?

■ Examples of resources:

People:

Equipment:

Consumable goods:

Natural resources:

Water, minerals

Fixed facilities:

Financial resources:

What is a resource?

■ Definition:

» A resource:

- Dictionary:
 - 1) A source of supply, support or aid;
 - 2) the collective wealth of a country;
 - 3) money, or any property that can be converted into money.
- ORF411:
 - (1) An information class which constrains the system.
 - (2) An *endogenously* controllable information class which constrains the system.
 - (3) An information class that costs money to acquire.
- There are two important subcategories:
 - Active – These are resources which we can act on directly to change their attributes.
 - Passive – These are resources whose attributes cannot be changed (at least within the time frame of our actions).

What is a resource?

- What is a resource?

- ... an asset?

What is a resource?

■ Definition:

» An asset:

- Dictionary:

- 1) A useful thing or quality;
- 2) A single item of ownership having exchange value, especially those convertible to cash.

» Q: When is a resource not an asset?

What is a resource?

A clean state of mind, for all your environments.

Liquid Assets - Our Water Resources

Liquid Assets - Our Water Resources

Objectives

- ◆ To understand the relationships among water quality, water pollution, personal lifestyle, and the ecological health of the Lake Pontchartrain Basin.
- ◆ To develop an awareness of water resources and water quality.
- ◆ To understand the differences between point and non-point source pollution.

Multiple Intelligences Learning Activities

What is a resource?

■ In the entrance hall of the American Museum of Natural History

» *The next generation behaves well if it treats the natural resources as assets which it must turn over to the next generation increased and not impaired in value.*

» *President Theodore Roosevelt*

What is a resource?

- What is a resource?

- ... an asset?

- ... a commodity?

What is a resource?

■ What is a commodity?

» Business/economics:

- Food/agriculture:
 - Pork bellies
 - Grain
- Natural resources
 - Iron ore
 - Oil
- A product or service produced using widely available technology
 - TV's
 - Personal computers
 - Plastics

What is a resource?

■ What is a commodity?

- » Operations research: A type of flow
 - A type of product
 - Type of aircraft; type of good being moved
 - Flow with a known origin and destination
 - Passengers, packages, letters, freight
 - Messages
 - A specific entity
 - A person, a particular aircraft

x_{ij}^k = Flow of type k from i to j

What is a resource?

■ Definition (dynamic resource management)

» A “**commodity**” is a set of resources with a common set of static attributes (the commodity type) and a set of dynamic attributes:

- Fuel
 - Static attribute: octane
 - Dynamic attributes: location
- Aircraft
 - Static attribute: type of aircraft
 - Dynamic attributes: location, fuel, maintenance
- Pilot
 - Static attribute: ID (each pilot is a commodity)
 - Dynamic attributes: location, hours, qualification
- Passengers
 - Static attribute: origin/destination combination

What is a resource?

■ Special types of resources:

- » Many resource management problems can be described in terms of resources being used to accomplish tasks:

“Resources”	“Tasks”
Taxicab Hotel room Student Aircraft Pilot Drilling machine Programmer	Customer Guest Term paper Flight Aircraft Piece of metal Software bug

- » ... but the designation of “resource” and “task” can sometimes be arbitrary.

What is a resource?

■ What is a task?

» a.k.a.:

- Customer
- Job
- Order
- Demand
- Request
- Requirement
- Need

» All of these carry the connotation of an exogenous agent who will reward the process for a service.

» Sometimes there is more than one class of “exogenous agent”

What is a resource?

■ What is a task?

» Define the resources and tasks for:

- A management consulting firm needs to assign newly hired ORFE majors to work on consulting projects around the world.
- A semiconductor plant: wafers have to move through a sequence of machines before becoming a semiconductor.
- A pilot and aircraft are needed to move a set of passengers from Newark to Chicago.
- A locomotive, operated by a crew, has to pull a set of box cars from one location to the next.

What is a resource?

■ We can divide resources into six classes:

- » Physical
 - People
 - Objects (fixed, movable)
- » Financial
 - Money
 - Convertible assets
- » Informational
 - Phone calls, TV, WWW
 - Newspaper, books, magazines
- » Time
 - Years/months/days/hours/minutes/seconds
- » Energy
 - Calories, watts, horsepower, $E = mc^2$
- » Limits/targets
 - Risk
 - Corporate average fuel economy standards
 - Customer service constraints

What is a resource?

■ We can divide our resource classes into two broad groups:

» Active

- Physical
 - People
 - Objects (fixed, movable)
- Financial
 - Money
 - Convertible assets
- Informational
 - Phone calls, TV, WWW
 - Newspaper, books, magazines

» Passive

- Time
 - Years/months/days/hours/minutes/seconds
- Energy
 - Calories, kilowatts, horsepower, $E = mc^2$
- Limits/targets
 - Risk
 - Corporate average fuel economy (CAFÉ) standards for MPG
 - Customer service constraints

What is a resource?

■ Resource dimensions

- » “Resources” vs. “tasks”
 - Resources: actions on “resources” generate a negative contribution.
 - Tasks: actions on “tasks” generate a positive contribution.
- » Attributes
 - Static - the type of aircraft
 - Dynamic - its location.
- » Attribute space
 - No attributes
 - Single dynamic attribute
 - Single static attribute; single dynamic attribute
 - Multiple attributes
- » Actionability
 - Active - The aircraft.
 - Passive - The fuel.

What is a resource?

■ Resource dimensions:

» Persistence

- Persistent - resources which “hang around”
 - Perishable - food, passengers
 - Reusable - aircraft, pilots
- Transient

» Recurrence

- Recurrent -
 - Periodically returns to a base state (or set of states)
- Nonrecurrent

» Discreteness

- Discrete
- Continuous

Lecture outline

- 
- What is a resource?
 - Multilayer problems
 - Modeling resources
 - A battery storage application

Multilayered systems

■ Composite resource: Sandwich

» Primitive resource layers

- Bread
- Lettuce
- Tomatoes
- Meat

» Bundles:

- Four slices of tomato
- Four slices of cheese
- Two pieces of lettuce
- Three slides of meat

» Coupling of bundles – new behavior:

- Satisfies demand for lunch

Multilayered systems

■ Resource layering

- » Often we create more complex resources by combining (bundling and/or coupling) them
 - Pilots in an aircraft
 - Auto components assembled into a car
 - A portfolio of financial assets
 - A medical team with support staff, equipment and medicines.

Multilayered systems

- More composite resources:

Teams of people with different skill sets.

Multilayered systems

■ More composite resources:

Assembling components into products

Multilayered systems

■ More composite resources:

<i>Portfolio</i>	
<u>Asset</u>	<u>Value</u>
Microsoft	\$34,500
Dell	\$23,435
Cinema Theatres	\$12,400
General Motors	\$65,230
JP Morgan	\$17,650

Multilayered systems

- Problem complexity can often be measured by the number of resource layers...
 - » One layer
 - » Two layer
 - » Three layer
 - » ...
 - » Many layers

Multilayered systems

■ One layer problems:

- » Financial asset allocation problems
- » Classical inventory planning (but with no demand backlogging).
- » Distribution problems (possibly multiproduct) with stochastic demands (but no demand backlogging).
- » The dynamic travelling repairman problem.
- » Schedule aircraft
- » Rail operations I: distributing box cars to customers with no demand backlogging.
- » Electric power distribution, with storage.

Multilayered systems

■ Two layer problems:

- » Multi-skill call centers (technical support agents and customers)
- » Personnel planning (assigning people to jobs).
- » Taxi fleets (taxis and customers)
- » Truckload load matching (drivers and loads).
- » The postal service II: Routing shipments and trailers
- » Rail operations II: Scheduling locomotives to move trains.

Multilayered systems

■ Three layer problems:

- » Business jets – Pilots, aircraft, customers
- » Truckload trucking (driver, tractor and trailer).
- » Machine scheduling (with setups) with operators (jobs, machines and people).
- » The postal service III: routing shipments, trailers and drivers.
- » Rail operations III: Scheduling locomotives and crews to move trains.

The fractional jet ownership industry

Lecture outline

- What is a resource?
- Multilayer problems
- Modeling resources
- A battery storage application

Modeling resources

- Often, we are managing resource classes:

- » Money
- » Agricultural commodities

- If we have only one type of resource, we would use:

R_t = Scalar resource state vector (how much money, oil)

- If we have different types of resources:

R_{ti} = Number of resources of type $i \in I$

R_t = Resource state vector = $(R_{ti})_{i \in I}$

- If our resources have complex attributes:

R_{ta} = Number of resources with attribute $a \in A$

R_t = Resource state vector = $(R_{ta})_{a \in A}$

Modeling resources

■ Resource classes and attributes

\mathcal{C}^R = Set of resource classes

aircraft, people, oil, medications, money

\mathcal{A}^c = The space of attributes for resources in class c .

$a \in \mathcal{A}^c$ = The attributes of a resource in resource class c .

» Examples:

- Money
- Energy (oil/gas/coal)
- Blood (blood type)
- A car
- A person

$$a^{Aircraft} = \begin{bmatrix} \text{Aircraft type} \\ \text{Location} \\ \text{Fuel level} \end{bmatrix}$$

Modeling resources

- If we are modeling discrete entities, we might use:

$\mathcal{R}^c =$ Set of resources in class $c \in \mathcal{C}^R$

(a list of professors, list of aircraft, list of doctors)

$r \in \mathcal{R}^c$ would be a particular resource (e.g. an aircraft or doctor)

$a_r =$ Attribute of resource $r \in \mathcal{R}^c$

- Different types of resources within a class

- » Employees with different ages, skills
- » Money in different investments (stocks, bonds)
- » Baseball players (outfielders, shortstop, catcher,...)

- Resources in different classes

- » Doctors, waiting rooms, MRI machines
- » Pilot, aircraft, customer

Modeling resources

■ Major problem classes:

» Basic inventory problems:

$$a = [\quad]$$

» Multiproduct problems:

$$a = [\text{Class}]$$

» Single commodity flow problems:

$$a = [\text{State}]$$

» Multicommodity flow problems:

$$a = \begin{bmatrix} \text{Resource class} \\ \text{State} \end{bmatrix}$$

Modeling resources

■ Major problem classes:

» The heterogeneous resource allocation problem:

$$a^{Pilot} = \left[\begin{array}{c} \text{Home} \\ \text{A/C certification} \\ \text{Seniority} \\ \text{Current location} \\ \text{Duty hours} \end{array} \right] \left. \begin{array}{l} \} \\ \} \end{array} \right\} \begin{array}{l} \text{Static attributes = class} \\ \text{Dynamic attributes = state} \end{array}$$

» The multilayered resource scheduling problem:

$$a = \left[\begin{array}{c} a^{Pilot} \\ a^{Aircraft} \\ a^{Customer} \end{array} \right]$$

Modeling resources

■ A basic inventory problem

» Example:

- How many copies of a particular book should Amazon.com hold in stock?

» Resource variable:

$R_t =$ Amount of product in inventory at time t

» Decision variable:

$x_t =$ Amount of product to order in time t .

Modeling resources

■ A stochastic shortest path problem

» Example:

- We are trying to traverse a network. The cost C_{ij} from i to j is random. At node i , we get to see the actual cost to traverse from i to j , but not the costs out of j .

» Resource variable:

$$R_{ti} = 1 \text{ if we are at node } i.$$

» Decision variable:

$$x_{tij} = 1 \text{ if we choose to traverse from } i \text{ to } j.$$

Modeling resources

■ A single commodity flow problem

» Example:

- Distributing heating oil from refineries to storage facilities to customer tanks.
- Managing inventories of vaccines
- Controlling the flow of water between reservoirs

» Resource variable:

R_{ti} = Amount of product at location i at time t .

We call " i " the *resource state*.

» Decision variable:

x_{tij} = Amount of resources in state i to move to state j at time t .

Modeling resources

■ A multicommodity flow problem

» Example:

- Moving different types of computers from the manufacturing plant to distribution centers and retail outlets.
- Assigning different types of aircraft to serve flights.

» Resource variable:

R_{ti}^k = Amount of product k at location i at time t .

k is called the *commodity*.

» Decision variable:

x_{tij}^k = Amount of resources of type k in state i to move to state j at time t .

Modeling resources

■ A multiattribute problem

» Example:

- Assigning staff (people) in a company (e.g. IBM or HP) to different projects over time.
- Managing fleets of locomotives, capturing the attributes of maintenance, fuel, and orientation (which way is it pointed?)

» Resource variable:

a = Attributes of a person (or type of person)

R_{ta} = Amount of resources with attribute a at time t .

» Decision variable:

x_{tad} = Amount of resources with attribute a that we act on with decision d at time t .

Modeling resources

- What can we do to a resource?
 - » Buying/selling

 - » What to do
 - What path to take through a network
 - Where to invest money?
 - What job to take?
 - Who do you assign to a task?

 - » How much?
 - How much money to invest?
 - How many people should a company hire?
 - How large should the stock of vaccines be?

Modeling resources

■ Types of decisions

d = A type of decision (buy, sell, move, repair, consume)

\mathcal{D} = The set of decision types

■ The decision vector (a single type of resource)

x_{td} = The number of times (or amount of resources) we execute decision d at time t (how much to buy, sell, move)

$$x_t = (x_{td})_{d \in \mathcal{D}}$$

■ The decision vector (multiattribute resources)

x_{tad} = The number of times we act on a resource with attribute a with a decision of type d .

$$x_t = (x_{tad})_{a \in A, d \in \mathcal{D}}$$

Modeling resources

■ How does the system evolve?

» An inventory problem

$$R_{t+1} = \max \{0, R_t + x_t - D_t\}$$

» Shortest path problem

$$R_{t+1,j} = R_{ti} x_{tij} = \begin{cases} 1 & \text{if } R_{ti} = 1 \text{ and } x_{tij} = 1 \\ 0 & \text{Otherwise} \end{cases}$$

» Multiattribute problem (for complicated problems)

$$\delta_{a'}(a, d) = \begin{cases} 1 & \text{If decision } d \text{ acting on a resource w/ attrib } a \\ & \text{produces a resource with attribute } a' \\ 0 & \text{Otherwise} \end{cases}$$

$$R_{t+1,a'} = \sum_{d \in \mathcal{D}} \delta_{a'}(a, d) x_{tad}$$

Modeling resources

■ Objectives

- » Maximize profit/minimize cost
- » Maximize utility
- » Minimize (or control) risk
- » Meet goals
 - Multiple performance measures
- » Discuss multiple objectives that arise when managing:
 - Complex equipment (aircraft, locomotives)
 - People (e.g. employees at IBM)

Modeling resources

■ Modeling a deterministic inventory problem

Variables:

R_t = Amount of inventory (money, energy, blood) available to be used at time t .

x_t = Amount ordered at time t (assume it arrives right away)

D_t = Demand during time interval t (between t and $t + 1$)

Basic transition function

$$R_{t+1} = R_t + x_t - D_t$$

Notes:

x_t = Represents resources that arrive immediately

D_t = Is demands to be served between t and $t + 1$, but known at time t

Modeling resources

■ How much do we order?

What if costs are linear?

$$\min_{x_0, x_1, \dots, x_T} \sum_{t=0}^T cx_t$$

Optimal solution is to order $x_t = D_t$

What if the cost function looks like:

$$C(x) = \begin{cases} 0 & x = 0 \\ K + cx & x > 0 \end{cases}$$

What if the costs depend on time:

$$\min_{x_0, x_1, \dots, x_T} \sum_{t=0}^T c_t x_t$$
